Implementation Summary

- **State management:** Provider, with separate providers for authentication, courses, and downloads.
- **Authentication:** Users are stored locally with shared_preferences. Passwords are stored as SHA-256 hashes, never in plain text. Seeded users from `users.json` are merged with accounts registered on the device. The session persists across app restarts until logout.
- **Course data:** Loaded from `assets/data/courses.json`. Each course has chapters, and each chapter has lessons with a title, description, duration, and video URL.
- **Video playback:** Uses video_player with chewie. A lesson plays from the local file when a download exists, otherwise it streams from the URL.
- **Offline downloads:** Uses dio to download MP4 files into the app documents directory located with path_provider. Progress is shown as a percentage. Download records are stored in local storage so they survive restarts.
- **Connectivity:** connectivity_plus detects when the device is offline so the app can show a clear message and still play downloaded lessons.
- **Screen wake:** wakelock_plus keeps the screen on during video playback.

Limitations

- Authentication is local and mock only. There is no backend, token handling, or password recovery, and accounts exist only on the device where they were created.
- Course videos are public sample MP4 files. Their availability depends on the hosting servers and the user's network.
- Only direct MP4 URLs can be downloaded. YouTube and other streaming-page URLs are not supported, as the assignment specifies.
- The lesson marked streaming-only is intentionally not downloadable.
- Lesson durations in the JSON are fixed values and may differ from the actual sample video length.
- Tested on Android only. iOS is not configured.
- Downloads are not resumed after the app is killed mid-download.

Search and lesson progress tracking are not implemented.
